Quantum Tunneling

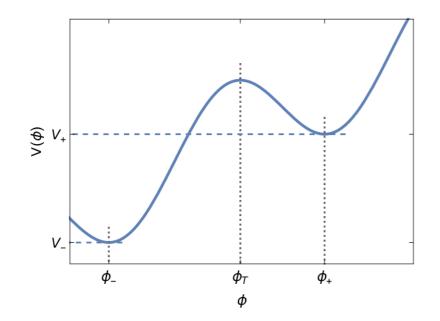

probability of vacuum decay per volume and time: $\Gamma = Ae^{-S/\hbar}$ "tunneling rate" sea of false vacuum bubble of true vacuum

Voloshin, Kobzarev, Okun 1974, Coleman 1977

S: action of the bounce (path of least residence)

$$\frac{d^2\phi}{d\rho^2} + \frac{3}{\rho}\frac{d\phi}{d\rho} = V'(\phi)$$
$$S \propto \int_{0}^{\infty} d\rho\rho^3 \left[\frac{1}{2}\left(\frac{d\phi}{d\rho}\right)^2 + V\right]$$

Bounce Action

thin-wall approximation:

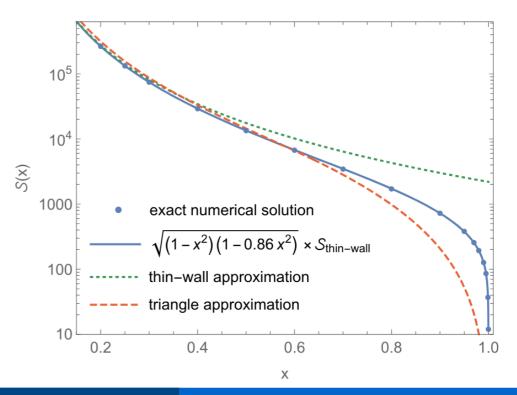

$$S_{thin-wall} = rac{4}{\pi} rac{f^4}{\Lambda^4} \left(rac{12}{x}
ight)^3$$

improved approximation:

$$\begin{split} \mathsf{S}_{\mathsf{improved}} &= \mathsf{S}_{\mathsf{thin-wall}} \\ & \times \sqrt{(1-\mathsf{x}^2)(1-0.86\mathsf{x}^2)} \end{split}$$

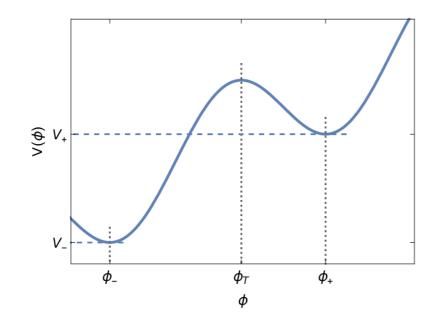

example potential:

$$V = \mu^{3}\phi + \Lambda^{4}\cos\frac{\phi}{f}$$
we define: $x = \frac{f\mu^{3}}{\Lambda^{4}}$

Quantum Tunneling in the Early Universe

Bounce Action

thin-wall approximation:

$${
m S}_{
m thin-wall} = rac{4}{\pi} rac{{
m f}^4}{{
m \Lambda}^4} \left(rac{12}{{
m x}}
ight)^3$$

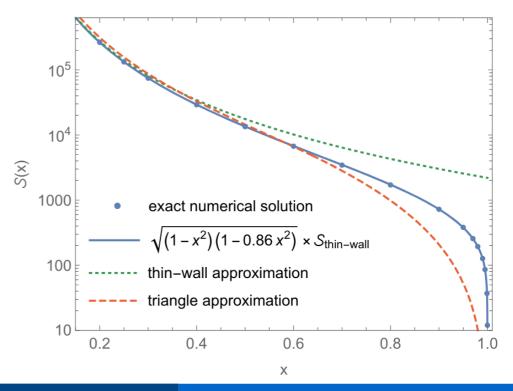

improved approximation:

$$\begin{split} \mathsf{S}_{\mathsf{improved}} &= \mathsf{S}_{\mathsf{thin-wall}} \\ & \times \sqrt{(1-\mathsf{x}^2)(1-0.86\mathsf{x}^2)} \end{split}$$

example potential:

$$V = \mu^{3}\phi + \Lambda^{4}\cos\frac{\phi}{f}$$
we define:
$$x = \frac{f\mu^{3}}{\Lambda^{4}}$$

$$x=1$$

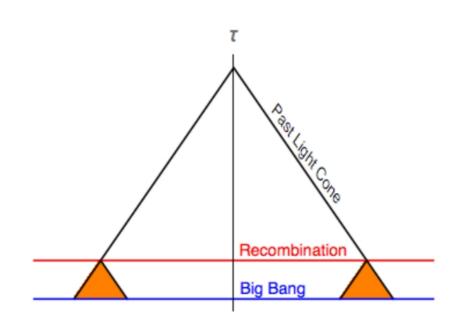

Quantum Tunneling in the Early Universe

Inflation

Guth 1981

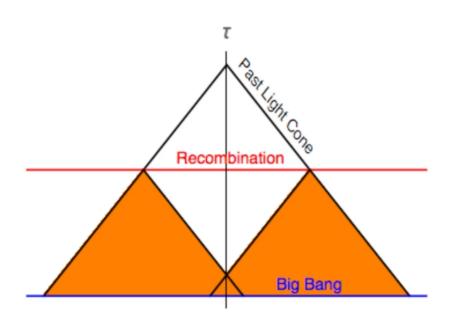

- solves horizon problem
- solves flatness problem
- dilutes dangerous relics

Inflation

Guth 1981

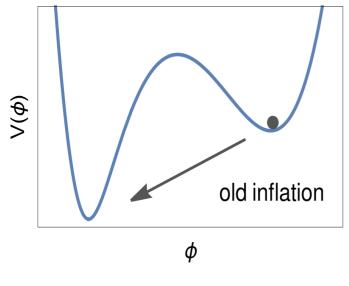

- solves horizon problem
- solves flatness problem
- dilutes dangerous relics

Old Inflation

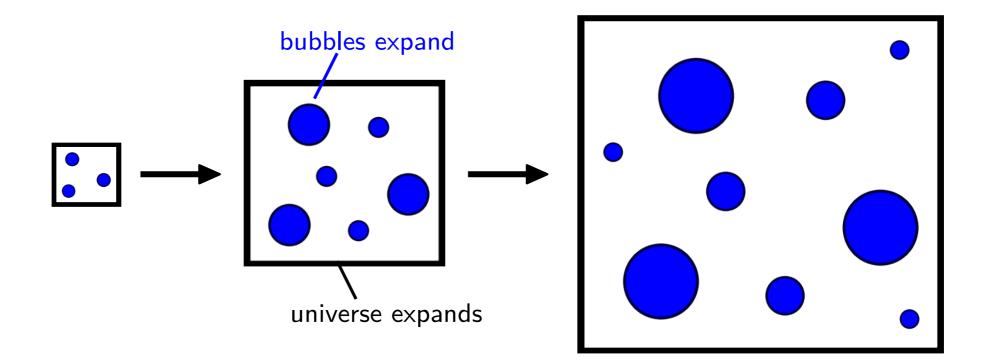

inflation driven by potential energy of the inflaton field

Inflation models

Guth 1981

 bubble formation rate = tunneling rate must be low enough to get 60 e-folds of inflation

bubbles don't percolate, no reheating, no particles

• volume of a single bubble created at time t_0

$$V_b\simeq \frac{4\pi}{9}e^{H(t-t_0)} \qquad (\text{for }t\gg t_0)$$

volume of all bubbles vs. volume of the universe

$$\frac{\sum V_{\rm b}}{V_{\rm tot}} = \frac{4\pi}{9} \frac{\Gamma}{{\rm H}^4}$$

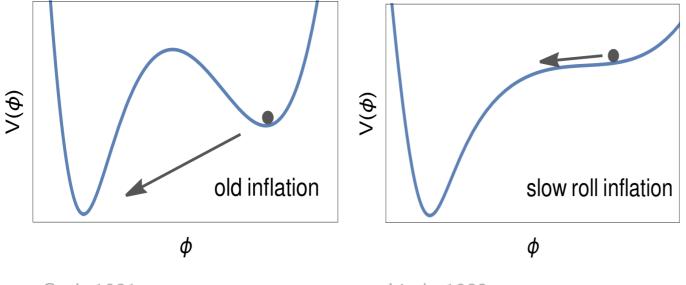

• bubble percolation hence requires $\Gamma/H^4 \gtrsim 1$

• inflation can only last for ~ 1 e-fold, but need 60 e-folds

Slow Roll Inflation

inflation driven by potential energy of the inflaton field

inflation models

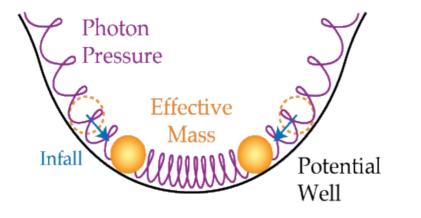

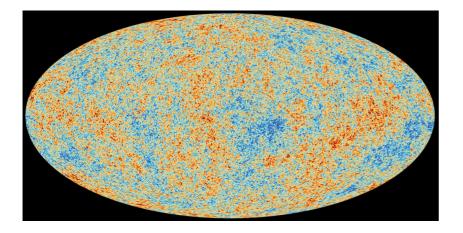

Guth 1981

Linde 1982 Albrecht, Steinhardt 1982

Slow Roll Inflation

 quantum fluctuations of the inflaton are stretched, reheating converts them into density fluctuations

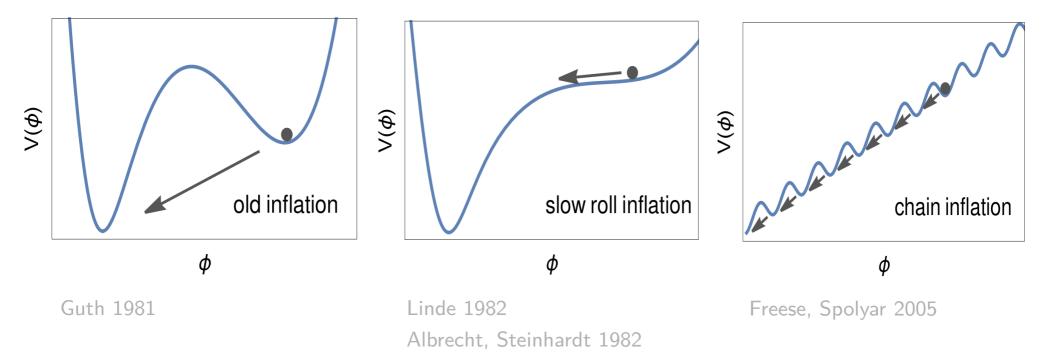

- create potential wells for baryon photon plasma
- acoustic oscillations due to radiation pressure
- CMB provides snaphot at last scattering

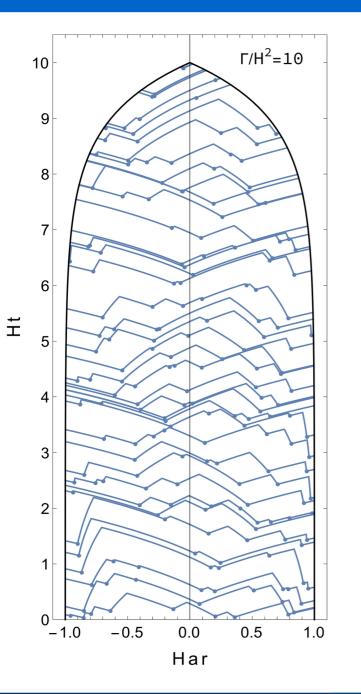

Chain Inflation

inflation driven by potential energy of the inflaton field

inflation models

Chain Inflation

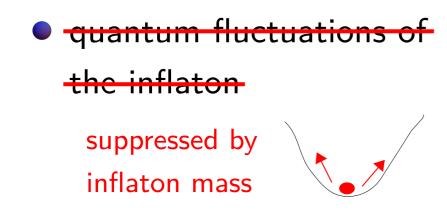

- inflaton tunnels along a series of false vacua of ever lower energy
- large Γ, bubbles are formed close to each other and percolate quickly
- bubble collisions create radiation
 which is quickly redshifted away
- what about the CMB?

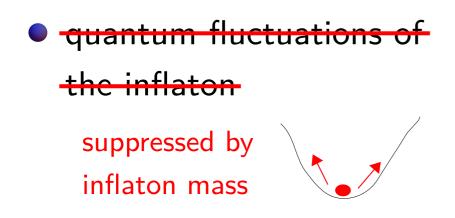

origin of fluctuations:

 quantum fluctuations of the inflaton

origin of fluctuations:

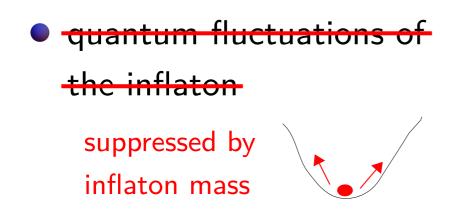

origin of fluctuations:

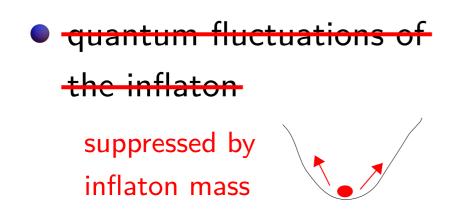

bubble wall collisions

origin of fluctuations:

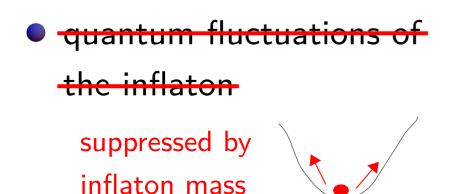

(bubble wall collisions)
 maybe, but complicated

origin of fluctuations:

- (bubble wall collisions) maybe, but complicated
- probabilistic nature of tunneling

origin of fluctuations:

- (bubble wall collisions) maybe, but complicated
- probabilistic nature of tunneling

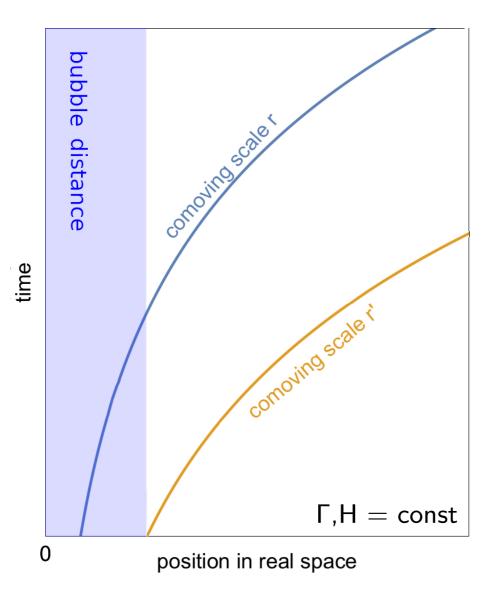

scalar power spectrum:

$$\Delta_{\mathcal{R}}^2 = \frac{H^2}{4\pi^2 c_s \epsilon} (-kc_s \eta)^{-2\epsilon}$$
$$\Delta_{\mathcal{R}}^2 = (0.04 \pm 0.02) \left(\frac{\Gamma}{H^4}\right)^{-0.42 \pm 0.03}$$
$$\Delta_{\mathcal{R}}^2 = \frac{H^2}{8\pi^2 \epsilon}$$
$$\Delta_{\mathcal{R}}^2 = \frac{H^2}{8\pi^2 \epsilon/\sqrt{3}}$$
$$\Delta_{\mathcal{R}}^2 = \frac{3}{4\pi} \frac{H^4}{\Gamma}$$

Watson et al. 2007, Feldstein, Tweedie 2007, Huang 2007, Chialva, Danielsson 2008 & 2009, Cline, Moore, Wang 2011

> literature in vast disagreement

Scalar Power Spectrum

two-point correlation:

 $\langle \delta \phi(\mathbf{r}) \delta \phi(\mathbf{0}) \rangle = \mathsf{var} \phi(\Delta t) + \mathsf{const}$

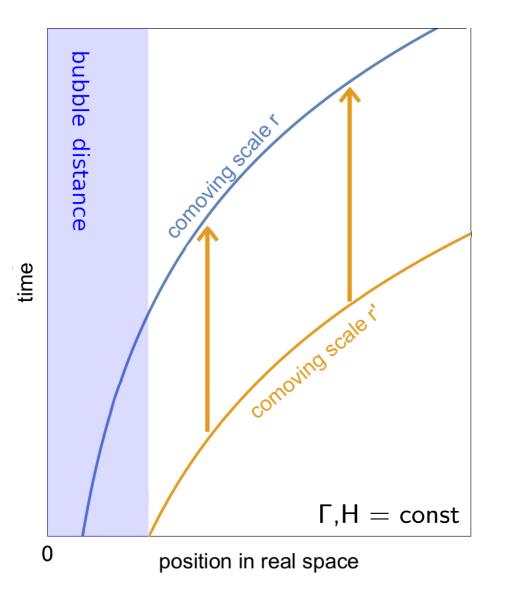

curvature perturbation

$$\mathcal{R} = \mathsf{H}\left(\frac{\mathsf{d}\langle\phi\rangle}{\mathsf{d}\mathsf{t}}\right)^{-1}\delta\phi$$

scalar power spectrum

$$\Delta_{\mathcal{R}}^2 = \left(\frac{\mathsf{d}\langle\phi\rangle}{\mathsf{H}\mathsf{d}\mathsf{t}}\right)^{-2} \frac{\mathsf{d}\mathsf{var}\phi}{\mathsf{H}\mathsf{d}\mathsf{t}}$$

Scalar Power Spectrum

two-point correlation:

 $\langle \delta \phi(\mathbf{r}) \delta \phi(\mathbf{0}) \rangle = \mathrm{var} \phi(\Delta \mathbf{t}) + \mathrm{const}$

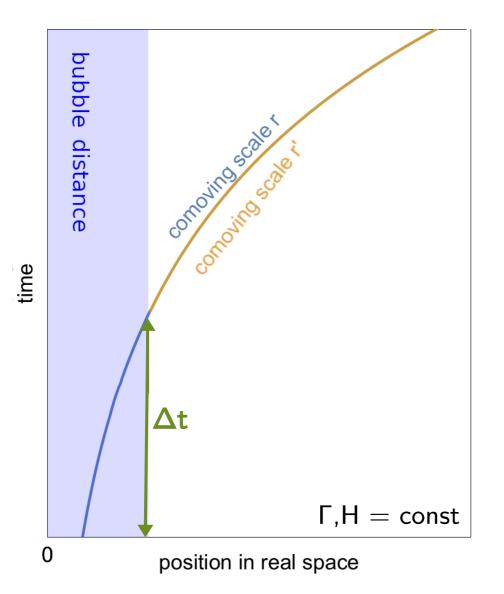

curvature perturbation

$$\mathcal{R} = \mathsf{H}\left(\frac{\mathsf{d}\langle\phi\rangle}{\mathsf{d}\mathsf{t}}\right)^{-1}\delta\phi$$

scalar power spectrum

$$\Delta_{\mathcal{R}}^2 = \left(\frac{\mathsf{d}\langle\phi\rangle}{\mathsf{H}\mathsf{d}\mathsf{t}}\right)^{-2} \frac{\mathsf{d}\mathsf{var}\phi}{\mathsf{H}\mathsf{d}\mathsf{t}}$$

Scalar Power Spectrum

two-point correlation:

 $\langle \delta \phi(\mathbf{r}) \delta \phi(\mathbf{0}) \rangle = \mathrm{var} \phi(\Delta t) + \mathrm{const}$

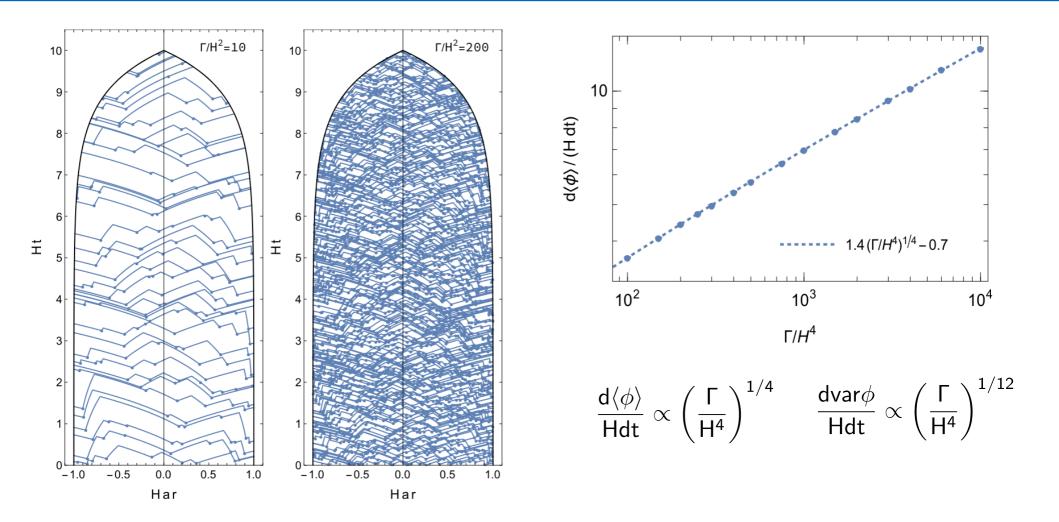

curvature perturbation

$$\mathcal{R} = \mathsf{H}\left(\frac{\mathsf{d}\langle\phi\rangle}{\mathsf{d}\mathsf{t}}\right)^{-1}\delta\phi$$

scalar power spectrum

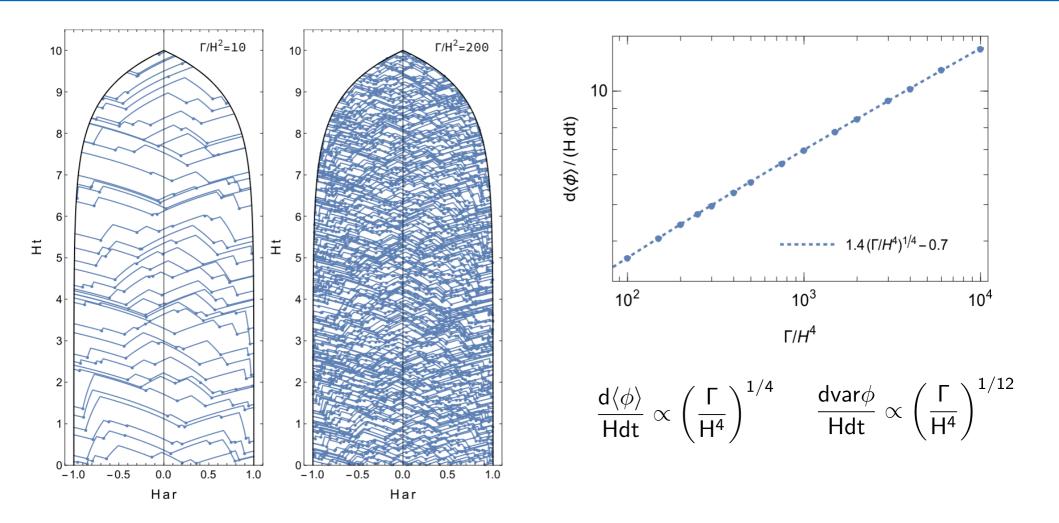

$$\Delta_{\mathcal{R}}^{2} = \left(\frac{\mathsf{d}\langle\phi\rangle}{\mathsf{H}\mathsf{d}\mathsf{t}}\right)^{-2} \frac{\mathsf{d}\mathsf{var}\phi}{\mathsf{H}\mathsf{d}\mathsf{t}}$$

Simulations

$$\Delta_{\mathcal{R}}^2 \simeq 0.06 \left(\frac{\Gamma}{H^4}\right)^{-5/12}$$

Simulations

$$\Delta_{\mathcal{R}}^2 \simeq 0.06 \left(\frac{\Gamma}{H^4}\right)^{-5/12}$$

$$\Delta_{\mathcal{R}}^2 = \left(0.04 \pm 0.02\right) \left(\frac{\Gamma}{\mathsf{H}^4}\right)^{-0.42 \pm 0.03}$$

Feldstein, Tweedie 2007

Quantum Tunneling in the Early Universe

Comparison with CMB

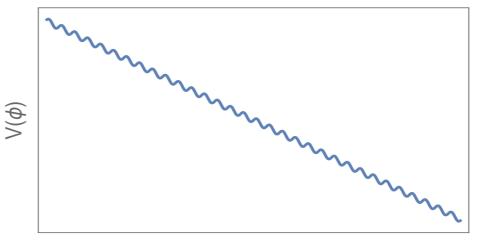

• COBE normalization $\Delta_{\mathcal{R}}^2 = 2 \times 10^{-9}$ implies

$$rac{\Gamma}{H^4} = 10^{18} \implies rac{vacuum transitions}{e-fold of inflation} \simeq \left(rac{\Gamma}{H^4}
ight)^{1/4} \simeq 4 imes 10^4$$

• scale-invariance of power spectrum broken by \dot{H} , $\dot{\Gamma}$

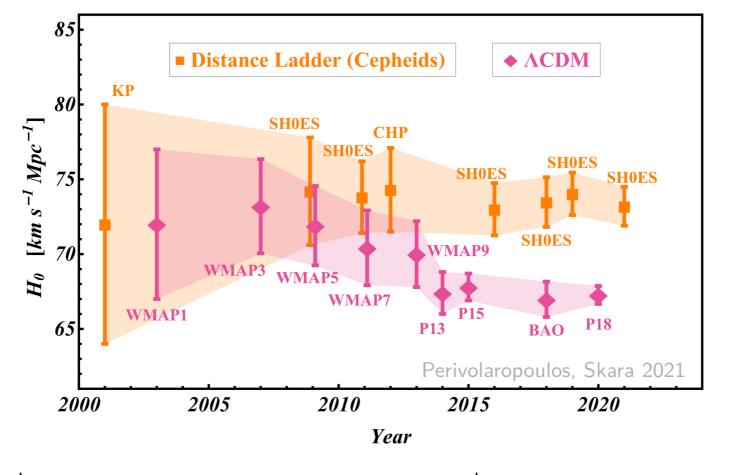

$$\mathsf{n_s} = 1 + \frac{5}{12} \left(\frac{4 \dot{H}}{H^2} - \frac{\dot{\Gamma}}{H\Gamma} \right)$$

$$n_s \simeq 1 - 0.03 \left(\frac{\Delta V}{10^{-6} \, V} \right)$$

Hubble Crisis

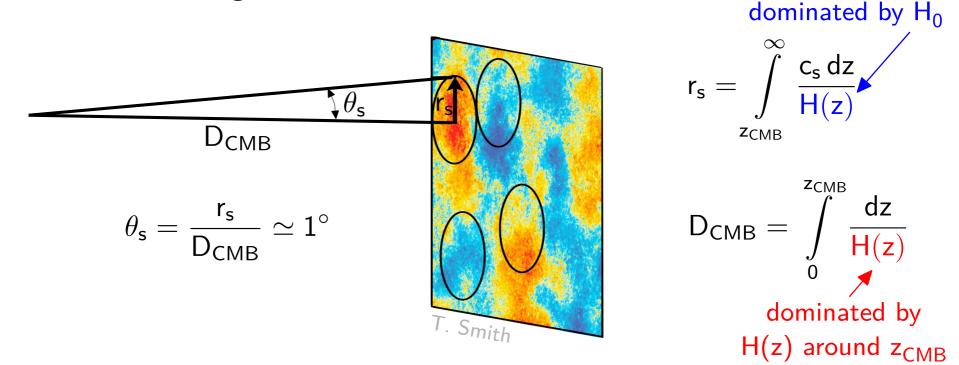

• H₀ disagrees between CMB and local measurements

$$\begin{split} H_0[\frac{km}{s\,Mpc}] &= 73.2 \pm 1.3 \ (\text{SH0ES}) \qquad H_0[\frac{km}{s\,Mpc}] = 67.3 \pm 0.6 \ (\text{Planck 2018}) \\ \text{Riess et al. 2021} \end{split}$$

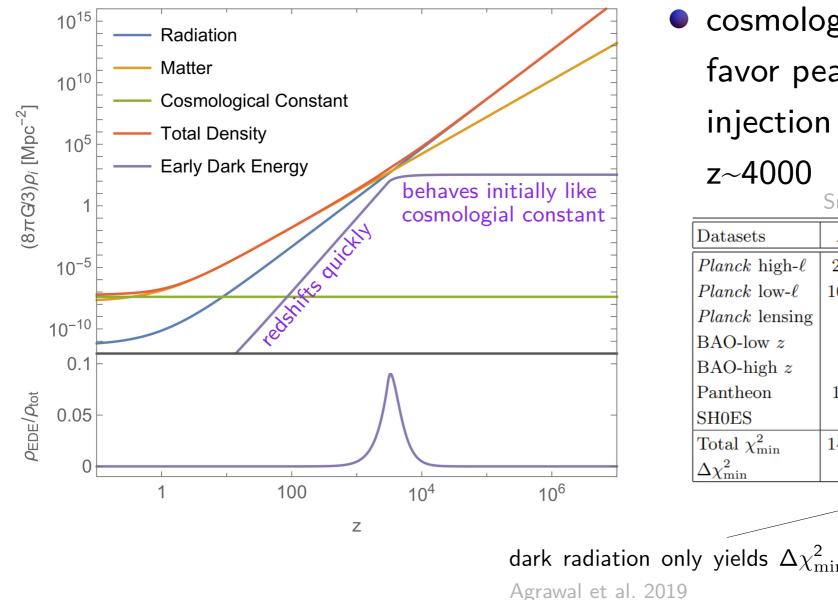

Early Time Solution

• CMB fixes angular size of sound horizon

- additional energy density before recombination reduces sound horizon
- fixed θ_s then requires larger $D_{CMB} \longrightarrow H_0$ increases

Early Dark Energy

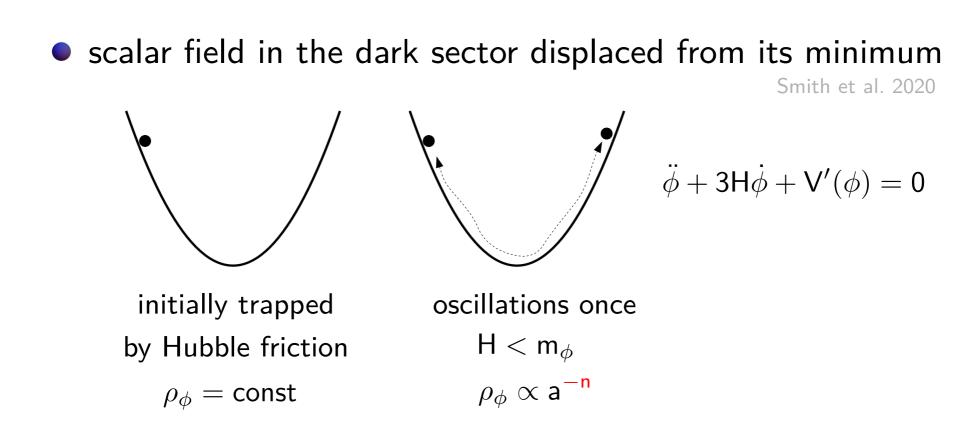

Karwal, Kamionkowski 2016, Poulin et al. 2018 & 2019

cosmological data favor peaked energy injection around Smith et al. 2020

| Datasets | ΛCDM | EDE |
|--------------------------|----------------------|----------|
| $Planck$ high- ℓ | 2446.66 | 2444 |
| $Planck$ low- ℓ | 10496.65 | 10493.25 |
| <i>Planck</i> lensing | 10.37 | 10.24 |
| BAO-low z | 1.86 | 2.53 |
| BAO-high z | 1.84 | 2.1 |
| Pantheon | 1027.04 | 1027.11 |
| SH0ES | 16.80 | 1.68 |
| Total $\chi^2_{\rm min}$ | 14001.23 | 13980.94 |
| $\Delta \chi^2_{ m min}$ | 0 | -20.29 |
| | | |

dark radiation only yields $\Delta \chi^2_{
m min} \simeq -4$

Oscillating Scalar Field Models

 <u>problem</u>: standard potentials yield too slow redshift (n~3), 'weird' potential required

 $V \sim \left(1 - \cos \frac{\phi}{f}\right)^3$

like non-relativistic matter

Early Dark Energy via Phase Transition

• dark sector scalar field trapped in false vacuum $\rho = \text{const}$

- bubbles of true vacuum, energy stored in bubble walls
- upon collision wall energy is transferred to

(1) anisotropic stress
$$\rho \propto a^{-6}$$
 (?)
(2) gravity waves $\rho \propto a^{-4}$ consistent with EDE
(3) dark radiation $\rho \propto a^{-4}$

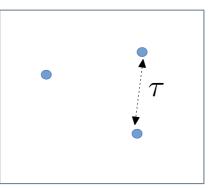

Niedermann, Sloth 2020 & 2021

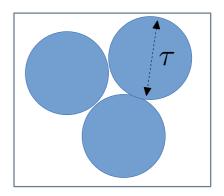

The Anisotropy Problem

required lifetime of the universe in the false vacuum

 $au \sim 2.5 imes 10^4 \, \text{yr} imes \left(rac{5000}{z}
ight)^2$ EDE solution $z_* \lesssim 5000$

• anisotropies of size $\Gamma^{-1/4} \sim au$ are formed

angular size of fluctuations at last scattering

 $\theta \simeq 0.1^{\circ} imes rac{5000}{z_{*}}$ CMB observations: $heta \gtrsim 0.05$ Large Scale Structure: $heta \simeq 0.002 - 0.2$

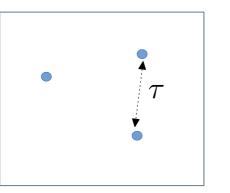

► CMB, LSS spoiled

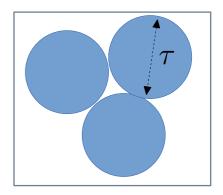

The Anisotropy Problem

required lifetime of the universe in the false vacuum

 $au \sim 2.5 imes 10^4 \ \text{yr} imes \left(\frac{5000}{z} \right)^2$ EDE solution $z_* \lesssim 5000$

including energy from bubble collisions:

$$\begin{aligned} &z \, \frac{\mathrm{d}\rho_{\phi}}{\mathrm{d}z} \ \simeq \ \frac{1.4 \, \Delta V \, \Gamma^{1/4}}{\mathrm{H}(z)} \\ &z \, \frac{\mathrm{d}\rho_{\mathrm{DS}}}{\mathrm{d}z} \ \simeq \ -\frac{1.4 \, \Delta V \, \Gamma^{1/4}}{\mathrm{H}(z)} + 3(1+\mathsf{w}) \, \rho_{\mathrm{DS}} \end{aligned}$$

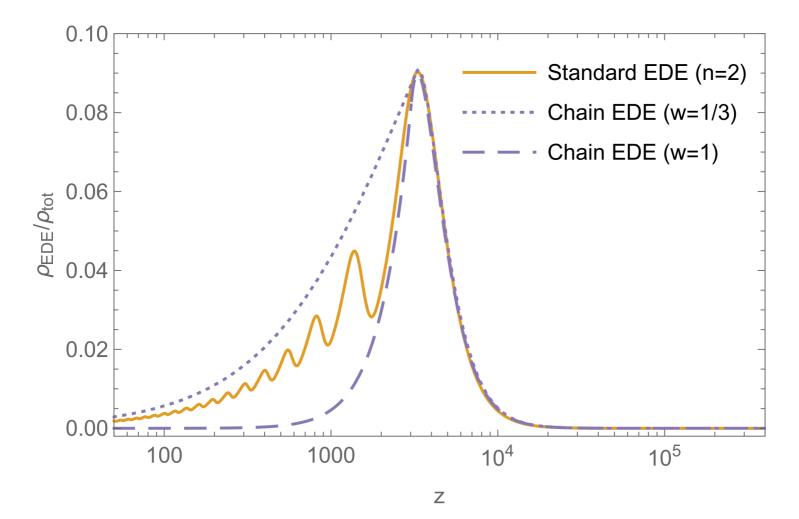

w = 1/3 (dark radiation) w = 1 (anisotropic stress)

 $\Gamma^{-1/4} \sim$ lifetime in single vacuum

 ΔV = energy difference between vacua

Comparison with Standard EDE

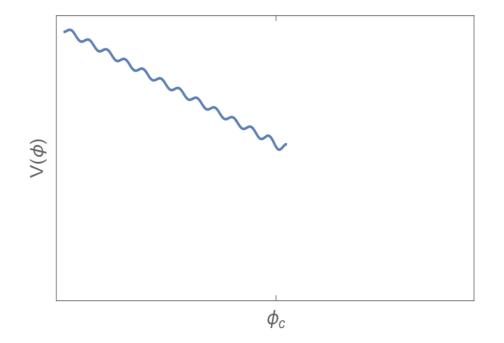

evolution of *P*EDE very similar to best-fit oscillating
 scalar field models
 solution to Hubble tension

Model Realization via Axions

• tilted cosine

$$\mathsf{V} = -\mathsf{g}\mathsf{M}^{3}\phi + \Lambda_{0}^{4}\cos\frac{\phi}{\mathsf{f}}$$

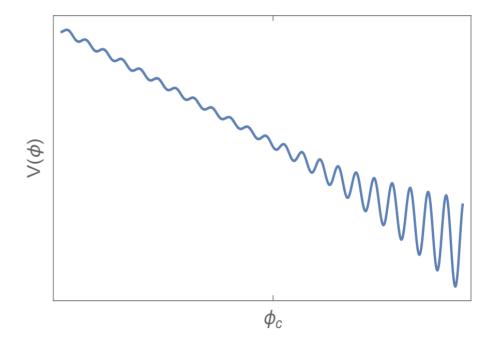

Model Realization via Axions

• tilted cosine + stopping

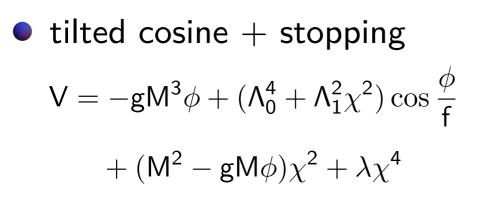

$$V = -gM^{3}\phi + (\Lambda_{0}^{4} + \Lambda_{1}^{2}\chi^{2})\cos\frac{\phi}{f}$$

$$+ (M^{2} - gM\phi)\chi^{2} + \lambda\chi^{4}$$

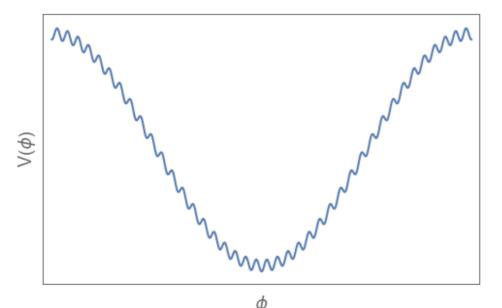

Graham, Kaplan, Rajendran 2015

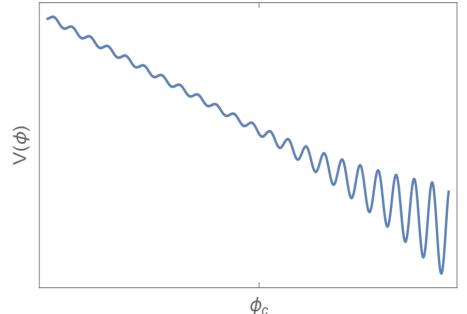

Model Realization via Axions
