Single-chain and condensed-state behavior of hnRNPA1 from molecular simulations

Intrinsically disordered proteins (IDPs) are essential components for the formation

of membraneless organelles, which play key functional and regulatory roles within biological systems. These complex assemblies form and dissolve spontaneously

over time via liquid-liquid phase separation of IDPs. Mutations in their amino acid

sequence can alter their phase behavior, which has been linked to the emergence

of severe diseases such as cancer and neurodegenerative diseases including amyotrophic

lateral sclerosis. In this work, we study the conformation and phase behavior of a low-complexity domain of heterogeneous nuclear ribonucleoprotein A1

(hnRNPA1), using coarse-grained implicit solvent molecular dynamics simulations [1].

We systematically analyze how these properties are affected by the number of aromatic

residues within the examined sequences. We find a significant compaction

of the chains and an increase in the critical temperature with increasing number of

aromatic residues within the IDPs. Comparing single-chain and condensed state simulations,

we find much more collapsed polymer conformations in the dilute systems,

even at temperatures near the estimated θ -temperature of the solution. These observations

strongly support the hypothesis that aromatic residues play a dominant role for condensation, which is further corroborated by a detailed analysis of the intermolecular contacts, and conversely that important properties of condensates are

captured in coarse-grained simulations. Interestingly, we observe density inhomogeneities

within the condensates near criticality, which are driven by electrostatic interactions.

Finally, we find that the relatively small fraction of hydrophobic residues

in the IDPs results in interfacial tensions which are significantly lower compared to

typical combinations of immiscible simple liquids.
